## 1 Introduction

ufdbGuard is a URL filter software suite that can be used with the Squid web proxy to block unwanted web sites on the internet. URLfilterDB is the URL database that ufdbGuard uses to determine which web sites are restricted. ufdbGuard also features the capability to enforce Google's SafeSearch, HTTPS tunnel detection and verification of HTTPS/SSL certificates.

You may register as a trial user at [www.urlfilterdb.com](http://www.urlfilterdb.com) to receive a 60-day trial license for the URL database. The trial license is for an operational URL filter without restrictions.

Internet access restriction tools are usually implemented to increase the productivity and shield users from unwanted web content. ufdbGuard is also a network protection tool blocking access to proxies and tunnels.

To be able to use an internet access restriction tool, it is necessary to have a well-defined internet usage policy. It is common to actively share this policy with all employees and define clearly what is expected from employees.

### 1.1 What is URL Filtering?

URL filtering is a mechanism to block access to certain types of websites. Usually the reason to use URL filtering is to achieve higher productivity and to lower bandwidth usage. By only blocking advertisements and file sharing sites (p2p) the internet bandwidth usage can drop considerably. A URL filter can also block adult sites and prevent access to websites where an individual can copy an internal document to this public website with one or two mouse clicks. Finally, a URL filter can protect the IT infrastructure by blocking access to websites that promote themselves as "safe" but are not.

Users browse the internet and often without knowing it, they usually use a web proxy like Squid that is in between a PC and the internet. Squid and ufdbGuard can verify if a user has access to a particular (part of) a website that is visited. Approved websites can be visited without restriction. In case that a (part of) a website is restricted; the web displays a message that access is prohibited.

### 1.2 Why is Tunnel Detection a Must-Have ?

Users who want to circumvent company internet and security policies, may use so-called *tunnels* to break through the firewall that protects your internal network from attacks from the outside. Tunnels can be extremely harmful since they circumvent firewall rules, the anti-virus protection is circumvented and tunnels can be *bidirectional*, i.e. the firewall is open to attacks from the outside through the tunnel. ufdbGuard detects and blocks these tunnels.

***SSH tunnels are one of the most dangerous types of tunnels where an entire corporate LAN can be exposed to anybody on the internet. Tunnels transfer firewalls into open doors!***

Very little knowledge is required to make a tunnel: everyone who knows how to type "how to punch holes in firewalls" at a search engine can do it. The reader is urged to get familiar with the risks of (SSH) tunnels to be able to implement a proper security fence. Security officers and senior management are advised to verify that a security solution is implemented to block tunnels.

### 1.3 Latest Major Enhancements

Version 1.23 was ported to OpenBSD and supports time-based ACLs which are usually used to relax filtering rules after a certain time. It also has a significant performance improvement of 20% to 96% depending on which URL categories are used. A new option to block/allow Skype was introduced.

Version 1.24 introduced options to monitor the URL filter by email and command script execution and has new configuration parameters to define how to behave in case of a fatal error or during a database reload. Ufdbguardd also reports on the status of the license and gives a warning if it expires in 2 months or less.

Version 1.27 supports detection of Facebook Chat. `ufdbAnalyse` can generate reports from multiple log files.

Version 1.28 introduces support for the educational filter of YouTube.

Version 1.29 introduces support for use of the anti-phishing URL list of PhishTank ([www.phishtank.com](http://www.phishtank.com)) and has a large performance improvement when reloading the configuration and URL database.

Version 1.30 introduces easier integration with LDAP-based and other databases with usernames.

A detailed list of all changes can be found at the top level of the source tree in the file `CHANGELOG`.

## 1.4 Copyright

The `ufdbGuard` software suite version 1.x is free. To protect the ownership and the freedom of use of `ufdbGuard`, there is a copyright and you have a license to use and modify the software freely, known as the GPL version 2 license. The license is here: [www.gnu.org/licenses/old-licenses/gpl-2.0.html](http://www.gnu.org/licenses/old-licenses/gpl-2.0.html).

The software suite is divided in 2 packages known as *ufdbguardd* and the *ufdbguardd API*. `Ufdbguardd` is inspired by `squidGuard` and parts of it are written by third parties and have a GPL2 copyright by those authors. The `ufdbguardd API` is meant to be used by vendors who wish to integrate URL filtering in their products and does not contain any code of third parties.

The URL database is a commercial product and has a copyright by URLfilterDB. A license is required to use the URL database which is defined in The Terms of Contract document that can be downloaded at the website: [www.urlfilterdb.com](http://www.urlfilterdb.com).

## 1.5 Support and Feedback

We welcome feedback from clients and those who test our software. Feel free to send your questions and feedback to the support desk: [support@urlfilterdb.com](mailto:support@urlfilterdb.com).

## 2 Prerequisites

ufdbGuard runs on all flavors of UNIX and is usually installed on the same system where Squid is installed. The Squid proxy software can be downloaded at [www.squid-cache.org](http://www.squid-cache.org).

ufdbGuard needs 2 GB disk space and 200 MB memory for the 32-bit version and 350 MB memory for the 64-bit version. The required CPU power is compared to Squid relatively low, so it can run on one CPU for small to medium sized user groups. For large user groups, it is highly recommended to use a multicore system and to use top-of-the-line servers for very large environments.

ufdbGuard uses probes to HTTPS sites to verify SSL certificates and to detect SSH tunnels and proxies. For these features ufdGuard needs to be able to open direct communication channels with web servers. If any of these security enhancing features of ufdGuard are required, firewall configurations may need to be modified.

For all systems, ufdGuard must be compiled with a C compiler. Most UNIX distributions come with the free GNU C compiler, `gcc` (see also [gcc.gnu.org](http://gcc.gnu.org)) or a native C compiler. In addition, the `wget`, `make` and `install` commands are required which are all included in most UNIX distributions.

ufdbGuard uses a compressed database and therefore requires the compression library `bz2`. This library is installed on most UNIX systems. In case that it is not on your system, it can be installed from your UNIX distribution CDs or downloaded from [www.bzip.org](http://www.bzip.org). It also uses `openssl` and needs the `openssl` header files which are included in your UNIX distribution (usually the package name is `openssl-devel`).

Starting with version 1.24 it is recommended to install the `gdb` debugging package to receive detailed information in the event that `ufdbguardd` terminates unexpectedly.

## 3 Architecture

Squid is a popular web proxy that is used as an internet cache and is usually part of the internet security solution where users are not given direct access to the internet. Squid is free and can be downloaded from [www.squid-cache.org](http://www.squid-cache.org).

Squid uses child processes called *redirectors* or *URL rewriters* to verify URLs for blocking. The redirectors are lightweight processes (`ufdbgclient`) that communicate with a multithreaded daemon process (`ufdbguardd`). The multithreaded daemon has only one copy of the URL database in memory and does the actual URL verification. The daemon sends a reply indicating OK or BLOCKED to the redirector which sends the answer to Squid.

The `ufdbguardd` daemon uses a UNIX socket to communicate with `ufdbgclient`. Alternatively, a TCP socket can be used with port 3977. `ufdbguardd` and `ufdbgclient` can be configured to use an alternative TCP port number.

To analyse SSL certificates of HTTPS sites, to detect proxies and SSL tunnels, and to detect various chat protocols, ufdGuard connects directly to web servers on the internet and probes the web servers independently. Therefore ufdGuard needs to be installed on a server that has direct internet access. Usually such server resides within a DMZ. A DMZ is not a requirement by ufdGuard but a DMZ is highly recommended for all corporate environments for reasons of security.

In the next simplified diagram, all pieces are put together: the web browser on a PC connects to the Squid web proxy who uses ufdGuard to block access to websites.

Figure 1: simplified architectural overview

Each request that Squid receives to retrieve a page from a website is first verified with ufdbGuard before Squid tries to fetch the content of the URL.

In case that the daemon is not running or when the daemon is loading a new version of the URL database, all URL verifications get an immediate OK and no web site is blocked. A database reload typically takes between 3 and 6 seconds.

ufdbGuard can be used with any URL database that comes in either a flat file format or the proprietary .ufdb format. The ufdbGuard software suite comes with a utility to generate an .ufdb database file from a flat file.

### 3.1 URL redirection

Squid sends each URL that it receives from a browser to ufdbGuard for inspection. If ufdbGuard finds a URL that needs to be blocked according to the local internet usage policy, it sends a substitution URL to Squid. This substitution URL is then used by Squid and content of the substitution URL is sent back to the browser.

A substitution URL is by default similar to this:

```
http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi?
category=adult&username=John&url=www.sex.com
```

So for each blocked URL, an appropriate message is retrieved which was generated by URLblocked.cgi at cgibin.urlfilterdb.com.

For reasons of efficiency, it is recommended to use the lightweight http daemon, ufdbhttpd, which has a built-in URLblocked.cgi. ufdbhttpd is part of the ufdbGuard software suite, can easily serve 700 requests/sec, and is recommended for all environments except the very large ones. Users of ufdbGuard which generate a very large number of hits on URLblocked.cgi on the server cgibin.urlfilterdb.com will be asked to stop using it.

Very large environments should use a web server on their LAN and install `URLblocked.cgi` on a web server. The web server must be able to incorporate perl scripts.

It is recommended **not** to redirect to a simple HTML page because not all blocked web objects are HTML-based objects. `URLblocked.cgi` produces an image for blocked images and produces a valid javascript document for blocked javascript objects, etc. If a blocked image is redirected to an HTML page, the browser receives HTML code where it expects an image and gets confused, may generate errors, or become slow.

## 3.2 Dynamic Proxy Tunnel Detection

The HTTPS protocol is encrypted and designed for secure online transactions like online banking and is considered a safe protocol since it cannot be decrypted. Unfortunately, the HTTPS protocol is at the same time a security risk since anybody can type "proxy tunnel" at Google and find out how to transfer data to and from any system on the internet *bypassing firewalls and internet access security measurements* using the HTTPS protocol. This is possible since HTTPS is encrypted and most security measurements like anti-virus software, malware detection and intrusion detection systems cannot scan encrypted data.

ufdbGuard has a unique protection mechanism that detects abuse of the HTTPS protocol and blocks all unauthorized transfers of data with these so-called proxy tunnels. When a URL with the HTTPS protocol is evaluated by ufdbGuard, ufdbGuard opens a separate connection to the web server and probes it for SSH tunnels, proxies, various chat protocols and valid SSL certificates. The results of the probes are cached to ensure a good performance.

Proxy tunnels can also be used with reverse port forwarding (using ssh) which means that from any system on the internet an unauthorized connection can be made into the protected network. It also does not matter how good the firewall is! As long as HTTPS is allowed and there is not a proper countermeasure against proxy tunnels, a high security risk exists.

The ufdbguardd daemon verifies all websites that are accessed with the HTTPS protocol and detects all popular proxy tunnels.

## 3.3 Enhanced HTTPS Security

As stated earlier, the HTTPS protocol is a useful protocol where secrecy is desired. Financial transactions are a good example where HTTPS is desired. Unfortunately, because HTTPS is encrypted, the HTTPS protocol is also used by applications that may introduce security issues like proxy tunnels, remote access software and viruses. To enhance the security of HTTPS connections on the internet, two configuration options control the use of HTTPS. See section 5.4 for more information.

# 4 Software Installation

It is assumed that the Squid web proxy is already installed, configured and operational. Please refer to the documentation of Squid to make it operational (see also [www.squid-cache.org](http://www.squid-cache.org)).

## 4.1 Upgrading from a Previous Version

A previous version can simply be overwritten by a new version.

CAVEAT: you must stop squid and ufdbGuard to overwrite executables, so you must stop them before a 'make install'.

When an upgrade is performed, it is recommended to perform all installation steps including the last step, retrieval of database update in section 4.8.

When an upgrade is performed, the default configuration file (`ufdbGuard.conf`) is not installed to prevent loss of previous settings. It is recommended to read the sections about configuration options and to add settings for the new options to the existing configuration file.

**NOTE:** when upgrading, the `make install` verifies the current configuration file and adds new URL categories if they do not exist. Always look carefully at the output that `make install` produces.

**NOTE:** starting with version 1.23, on systems that support configuration files in `/etc/sysconfig`, a new configuration file `/etc/sysconfig/uftdbguard` is used. Anybody who has modified the start script in `/etc/init.d/uftdb` may need to edit the new configuration file. During the installation a message reminds the administrator of the new file.

**NOTE:** starting with version 1.23, the installation defaults have changed. The configure script now has a default installation user `uftdb` (was `squid`) and a new default installation directory `/usr/local/uftdbguard` (was `/usr/local/squid`). The defaults can be changed with the configuration options `--with-uftdb-user` and `--prefix`.

## 4.2 User Account

The `uftdbGuard` software suite should be installed with its own user account, `uftdb`. Formerly, it was recommended to use the username `squid`, but this is now considered inappropriate because two different applications should have two different application owners. There is no technical reason not to use `squid` as the owner of the `uftdbGuard` package, so if you do not agree you can overrule the default by using user `squid` when running `configure`, see section 4.5 for details.

The user account must be a regular user account with credentials to login with a shell and be allowed to use `crontab`. It is recommended to use a new group and make the user the only member of the new group. It is suggested to use the groupname `uftdb`.

**NOTE:** the following steps in this section should be done as the aforementioned user.

## 4.3 Installation Directory

`uftdbGuard` can be installed in any directory and by default is installed in `/usr/local/uftdbguard`. In this manual, the word `TOPDIR` refers to the top level installation directory for `uftdbGuard`.

## 4.4 Unpack Software

The tar file that contains the `uftdbGuard` software suite must be unpacked in a source directory of your choice, e.g. `/local/src`.

Unpack the `uftdbGuard` tar file in the source directory:

```
$ cd /local/src
$ tar xzf uftdbGuard-latest.tar.gz
```

A directory with the name `uftdbGuard-1.30` contains the software.

## 4.5 Configure the Software Build

Before `uftdbGuard` is compiled, it needs to be configured and told what the `TOPDIR` of your choice is:

```
$ cd uftdbGuard-1.30
$ ./configure --prefix=TOPDIR
```

So, assuming that `TOPDIR` is `/usr/local/uftdbguard`, the `configure` command becomes:

```
$ ./configure --prefix=/usr/local/uftdbguard
```

The command `./configure --help` displays a description on how to configure alternative locations and username.

**NEW:** `UftdbGuard` is installed with the assumption that the user `uftdb` is owner of the installed files. If you prefer that `uftdbGuard` is installed with a different user account, you may use the `--with-uftdb-user` option. The administrator should create such a user account and the `configure` script reminds the

administrator of this. Since previous versions used a default user 'squid', you may want to use `--with-ufdb-user=squid`.

The most common error is that the *development* packages for openssl and bzip are not installed. The configure command checks for the existence of these packages and gives an appropriate message. For most operating systems, one can find the packages *openssl-devel* and *bzip2-devel* on the installation media. Note that each Linux distribution uses different package names and you may find that openssl-devel has an other similar name like *libssl-dev*. Likewise, the bzip2-devel package may be called *libbz-dev*. Refer to the Operating System manual on how to install additional packages.

## 4.5.1 Configure Software for Multiple Systems

ufdbGuard will use UNIX sockets whenever they are available which implies that ufdGuard and Squid must be executed on the *same system*. Alternatively, the less efficient TCP sockets can be used which have the benefit that Squid and ufdGuard can be executed on multiple systems. The choice for the type of sockets is made when the software is build; it is not a runtime configuration option.

To force the usage of TCP sockets, use the configure command with the option `--without-unix-sockets`. This option must be used if ufdGuard runs on a different system then where Squid runs.

## 4.6 Compile Software

Now compile the software suite:

```
$ make all
```

And ignore warnings about compiler options.

## 4.7 Install Software

In case that you perform an upgrade and squid is already running with ufdGuard client redirectors, squid must be stopped to be able to perform a proper installation. After the installation, squid is started after ufdGuard.

Stop any running instances of squid:

```
$ su -  
# /etc/init.d/squid stop
```

Stop any running instances of ufdGuard. i.e.

```
$ su -  
# /etc/init.d/ufdb stop
```

The programs can now be installed. Note that you must be root.

```
# cd ../ufdbGuard-1.30  
# make install
```

**Note:** the installation will look for an old configuration file and will update it and give feedback. The automatic updates are adding new URL categories (socialnet, extappl and p2p) and replacing references to [www.urlfilterdb.com/cgi-bin/URLblocked.cgi](http://www.urlfilterdb.com/cgi-bin/URLblocked.cgi) with [cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi](http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi) to offload [www.urlfilterdb.com](http://www.urlfilterdb.com). It is recommended to read the output of this installation step and to modify the ACLs where necessary.

It is recommended to start the ufdGuard daemon at system boot and before Squid is started. The start script is in the `init.d` directory (this may vary and depends on the OS). Optionally modify `UFDB_OPTIONS` to use the `-T` option to use the test mode.

And then start ufdGuard and Squid – in this order only.

```
# /etc/init.d/ufdb start
# /etc/init.d/squid start
```

## 4.8 Get Daily Updates

The script `ufdbUpdate` takes care of downloading a new version of the URL database and signaling `ufdbGuard` that a new version is downloaded. Daily updates are available for everyone with a permanent or trial license of URLfilterDB. The `ufdbUpdate` script should be run twice per day by the cron scheduler. There are 3 things to do:

- make sure that the `ufdb` user is allowed to run `crontab` jobs (`crontab -l` run as user `ufdb` should give no errors)
- enter the username and password in `ufdbUpdate` that you received when you purchased a license or received a trial license.
- choose an appropriate time at the end of the day and in the early morning to run `ufdbUpdate`

Edit the `ufdbUpdate` script to include the username and password that you received when the (trial) license was received:

```
$ vi /usr/local/ufdbguard/bin/ufdbUpdate
...
DOWNLOAD_USER=lic99999
DOWNLOAD_PASSWORD=aa22bb
```

Users that evaluate the URL database may use the `demoXX` username and password.

Test the `ufdbUpdate` script with the verbose option:

```
# su - squid
$ /usr/local/ufdbguard/bin/ufdbUpdate -v
```

The output should be similar to:

```
http_proxy is not set: no proxy is used for downloads
Downloading the current database...
<retrieving URL database>
new database downloaded:
-rw-r--r-- 1 root root 5121312 Dec 6 18:04 /tmp/urlfilterdb-latest.tar.gz
Unpacking the database...
The downloaded database is installed in directory /local/squid/blacklists and its
subdirectories
Sending HUP signal to the ufdbguardd daemon to load new configuration...
URL database creation date: Fri Jun 24 13:30:47 CEST 2011
<retrieving license status>
URL database license status: OK
done.
```

To install the cron job for `ufdbUpdate`, edit the `crontab` table of the user `ufdb` and add the appropriate lines:

```
$ crontab -e
```

To run the URL database update each day at 10:00 PM and 6:15 AM, add these two lines:

```
00 22 * * * /usr/local/ufdbguard/bin/ufdbUpdate
15 6 * * * /usr/local/ufdbguard/bin/ufdbUpdate
```

At this time, you may want to verify that the Squid housekeeping is also executed. Verify that the `crontab` for user `squid` has an entry to run “`squid -k rotate`” (see the squid manuals for more details). It is

a common misconception that this command only rotates the logfile of Squid but it also does necessary housekeeping. Note that the Squid housekeeping must be done when there is almost no load (e.g. at 03:00 AM).

## 4.8.1 Exit Codes of ufdbUpdate

To monitor URL database updates, ufdbUpdate has a defined set of exit codes.

<i>code</i>	<i>explanation</i>
0	all OK
1	version mismatch warning; most likely there is a new version of ufdbguardd
2	license expiration warning: less than 2 months to renew license
3	license expired: a license renewal is required immediately
11	configuration error
12	temporary file error
13	download OK but cannot signal ufdbguardd
21-40	exit code of ufdbUpdate is exit code of wget + 20. wget is the command that downloads the new URL database from the servers of URLfilterDB.
41-60	exit code of ufdbUpdate is exit code of gunzip + 40. gunzip uncompresses the downloaded URL database. There may be an issue with file system space.
61-80	exit code of ufdbUpdate is exit code of tar + 60. tar unpacks the downloaded URL database. There may be an issue with file system space.

In case of an error, it is advised to run `ufdbUpdate -v` from the command line to have more feedback about what is going wrong. License expiration warnings are also issued by ufdbguardd.

## 4.9 Firewall and Proxy Settings

### 4.9.1 ufdbGuard

ufdbGuard sends probes to HTTPS sites to detect tunnels, detect proxies, detect Skype, detect Google Talk, other chat applications, and verifies SSL certificates. It also sends statistics to the servers of URLfilterDB. Since tunnel and proxy detection are considered an important feature, it is strongly recommended to modify firewall rules to provide access.

ufdbGuard needs access to port 443 for all internet addresses and needs access to port 80 of `updates.urlfilterdb.com`.

### 4.9.2 ufdbUpdate

ufdbUpdate downloads the URL database and obviously needs access to the servers of URLfilterDB. Firewall rules may need to be modified to provide access to `updates.urlfilterdb.com`.

A proxy can be used to download the URL database: edit the ufdbUpdate script and assign the appropriate values to the variables `http_proxy`, `PROXY_USER` and `PROXY_PASSWORD`.

## 4.10 Database Updates from Other Sources

In case that a URL database is used that is not provided by URLfilterDB, the URL database is most likely a collection of flat files with domain names and URLs. In this case the user should implement itself a method for getting regular database updates. After downloading a new flat file URL database, the database must be converted to the proprietary database format of ufdbguardd using the ufdbConvertDB tool.

### 4.10.1 Converting a URL Database

ufdbConvertDB converts a whole URL database without the need to call ufdbGenTable for each URL category. ufdbConvertDB requires one parameter which is the top level directory name where the URL database resides.

Example:

```
# /usr/local/ufdb/bin/ufdbConvertDB /usr/local/ufdb/blacklists
```

## 5 Configuration

This chapter and chapter 7 and 8 describe the features and configuration syntax for ufdbGuard in detail. Chapter 9 describes the GUI for the features. It is recommended to read first chapters 5, 7 and 8 to get a better understanding of all features before one starts to use the GUI.

### 5.1 Know your Internet Usage Policy

Before one can start with the configuration of ufdbGuard, an internet usage policy must already be defined and state which web site categories are considered unwanted and therefore must be blocked by ufdbGuard. The HR department might be a good starting point to find out which categories of the database must be used to block access to parts of the internet.

**Note:** the default configuration of ufdbGuard blocks only adult, security, p2p, proxies, gambling and warez. By default, ufdbGuard blocks all unsafe HTTPS connections with the options `enforce-https-with-hostname`, `enforce-https-official-certificate` and `https-prohibit-insecure-ssl2`.

The internet usage policy may block certain categories which need exceptions. E.g. the internet usage policy may prohibit visiting shops but an authority may decide to allow access to the local pizza delivery – which is usually included in the category shops – to provide a meal for those who do overtime. Or a policy may allow access to shops but block one or two particular shops. The URL categories *alwaysallow* and *alwaysdeny* are used to define these exceptions and contains URLs that should be allowed or denied according to the local policy. Section 7 explains on how to configure these categories.

ufdbGuard supports time-based ACLs which enable the implementation of internet usage policies that have different policies during different time of the day or week. With time-based ACLs it is, for example, possible to define that after working hours a different – usually more relaxed – policy is used. See section 8.5 for more information.

It is recommended to start with the URL filter in the test mode. In this mode, sites are not blocked but only logged in the log file. An analysis of the log file may help in defining the appropriate Internet Usage Policy and to find out which sites should never be blocked (see also section 7.1). At last a free tip: to prevent a storm at the help desk or system administrator, it is advised to inform users about (change in) the implementation of a URL filter *before* it is implemented and to allow users to request to define exceptions with the *alwaysallow* category.

The ufdbGuard software suite includes a tool to find out what type of sites are currently visited by analyzing the Squid log file. See section 11 for a detailed description of ufdbAnalyse. This tool can also be used in determining or adjusting the Internet Usage Policy.

## 5.2 Automatic Improvements of the URL Database

Although the URL database is updated daily, it may happen that some web sites are not included in the URL database and therefore users might be able to visit inappropriate websites. UfdbGuard has a configuration option to collect a sample of these uncategorized domains and to upload them to URLfilterDB for inclusion in the database. This option is ON by default. Privacy is guaranteed since no identification of client, source or user is included, just the domain name is registered for categorization. URLfilterDB has a privacy policy which prohibits sharing of any information with 3<sup>rd</sup> parties and all software tools of URLfilterDB strip all parts of (intermediate) data which may contain privacy-related items such as IP address, user name, password and query parameters. See also <http://www.urlfilterdb.com/en/privacystatement.html>.

To prevent analysis of uncategorized URLs, the `analyse-uncategorised-urls` configuration option must be set to `off`. *It is, however, highly recommended to leave this option ON to receive more updates in the URL database which results in better filtering.* URLfilterDB categorizes URLs as soon as possible to include them in the URL database.

## 5.3 Proxy Tunnel Detection

Proxy tunnels are a security risk and it is strongly recommended to use detection of proxy tunnels. Enable proxy tunnel detection in the configuration file `ufdbGuard.conf` with the following line:

```
check-proxy-tunnel queue-checks
```

This option queues checks for proxy tunnels to be detected a few seconds later. It means that a proxy *can* be used but only for 1-2 seconds. Alternatively, proxy tunnels can be detected in an aggressive mode, where all HTTPS traffic is tested for proxies *before* access is given. The aggressive mode introduces some delays for HTTPS traffic and is therefore only recommended in very high security environments. If proxy tunnels are allowed, the value for `check-proxy-tunnel` can be `off` or `log-only`. All valid options are:

```
check-proxy-tunnel queue-checks      # recommended
check-proxy-tunnel aggressive
check-proxy-tunnel log-only
check-proxy-tunnel off
```

**NOTE:** proxy tunnel detection depends on the usage of the category *proxies*. Only when the URL category *proxies* is blocked, the proxy detection is performed.

**NOTE:** when the “aggressive” detection method is used, the number of threads in the `ufdbguardd` daemon and the number of redirector processes must be increased to 64 (maximum is 128). Therefore, change in `squid.conf` the parameter `url_rewrite_children` to 64 and restart squid. To start the `ufdbguardd` daemon with 128 worker threads, the command line option `-w 128` must be used. To use this option, the variable `UFDB_OPTION` in `/etc/sysconfig/ufdbguard` (or the startup script) must be set to “-w 128” (maximum is 128).

## 5.4 Control HTTPS Usage

Most websites that use HTTPS for legitimate business reasons use an SSL certificate that is signed by a well-known certificate authority and have a fully qualified domain name in the URL for maximum security and a clear identification of the website, while most websites that use HTTPS for other reasons, have self-signed SSL certificates and IP addresses instead of domain names. HTTPS is usually secure enough to protect the connection from eavesdropping but has an old protocol option which is rarely used and insecure. The old and insecure SSLv2 protocol can be blocked by means of a configuration option.

`ufdbGuard` is able to detect a small subset of protocols used on port 443 on the internet: HTTPS (HTTP+SSL), Skype and other chat applications, SSH and proxies. When `ufdbguardd` probes port 443 it

is quite possible that it stumbles upon a port of a website that uses an unknown protocol. There is a configuration option to allow or block unknown protocols. The default is to allow such protocol since there are many sites which use port 443 to deliver video content or other application-specific content.

Access to HTTPS websites can be controlled with the following options.

The following options are default in `ufdbGuard.conf`:

```
enforce-https-with-hostname on
enforce-https-official-certificate on
https-prohibit-insecure-sslv2 on
allow-unknown-protocol-over-https on
```

It is recommended to keep these options set to “on” to have a increased protection level against phishing sites, proxies and websites with untrusted SSL certificates. In case that a legitimate website uses an IP address in the URL or an SSL certificate that is not signed by a trusted authority, it is recommended to add this site to the locally trusted websites (see section 7.1).

If the option `allow-unknown-protocol-over-https` is ON, `ufdbguardd` allows unknown protocols by URLs composed of an IP address and the HTTPS port (port 443). `ufdbGuard` detects regular SSL connections, SSH, Skype and other chat protocols. It is recommended to leave this option ON since many sites use URLs of this type for video and other applications.

It is mandatory to use these options *inside* the definition of the category “security”:

```
category security
{
    domainlist "security/domains"
    option      enforce-https-with-hostname on
    option      enforce-https-official-certificate on
    option      https-prohibit-insecure-sslv2 on
    option      allow-unknown-protocol-over-https on
    redirect    ...
}
```

Finally, include the category security into the ACLs (see section 5.7) to block HTTPS abuse.

**Note:** the option to verify HTTPS certificates only works when the URL database of URLfilterDB is used since the URL database includes the necessary SSL certificates to verify HTTPS websites. The CA certificates are in the file `.../security/cacerts`. In case that an alternative file with certificates needs to be used, one can be defined with the keyword `cacerts` which must be used inside the security category definition. The configuration file may look like this:

```
category security
{
    domainlist "security/domains"
    cacerts    "/usr/local/ufdbguardd/cacerts"
    ...
}
```

`ufdbGuard` can also be configured to use a directory with certificates. The keyword `cacerts-dir` followed by a quoted string indicates the name of this directory. `ufdbGuard` allows the following configurations:

- no `cacerts` and no `cacerts-dir` keywords: `ufdbGuards` uses the default builtin `cacerts` file,
- no `cacerts` but `cacerts-dir` keyword: `ufdbGuard` uses the configured directory,

- both `cacerts` and `cacerts-dir` keywords: `ufdbGuard` uses both (the file first and then the directory).

## 5.5 Which HTTP Server to use for Redirection Messages

Whenever a website is blocked, Squid receives a redirection URL from `ufdbguardd`. This URL must point to a web server that can display an appropriate error message. Version 1.15 introduced a new lightweight `http` daemon with a built-in `URLblocked.cgi`: `ufdbhttpd`.

There are 3 options for serving redirection messages:

1. use `ufdbhttpd` on a non-privileged port on host *myhost.mylan*:  
`http://myhost.mylan:8080/cgi-bin/URLblocked.cgi`
2. use the perl script `URLblocked.cgi` on your own internal web server:  
`http://myhost.mylan/cgi-bin/URLblocked.cgi`
3. use `URLblocked.cgi` of `URLfilterDB`:  
`http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi`

Option 1 is preferred for all but very large environments. Option 2 is preferred for very large environments. You need to have a web server like Apache with `mod_perl` or `FastCGI` enabled to implement option 2.

The default configuration file comes with option 3 preconfigured. If option 1 or 2 is used, the `redirect` statements must be changed accordingly. E.g., change the lines with

```
redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi?color=orange&...
into
```

```
redirect http://myhost.mylan:8080/cgi-bin/URLblocked.cgi?color=orange&...
ufdbhttpd is lightweight and can be installed on the same server where ufdbguardd is installed.
```

For option 2: the perl script `URLblocked.cgi` is included in the distribution in the directory `samples`. The perl script uses some images which are also in the `samples` directory and which need to be installed on the webserver. The reader is referred to the documentation of the used web server on how to install this perl script.

Redirection of HTTPS-based URLs is more complex. See the next section for more information.

## 5.6 Issue with redirection of HTTPS-based URLs

Squid requires that HTTP-based URLs are redirected to other HTTP-based URLs and that HTTPS-based URLs are redirected to other HTTPS-based URLs. This causes a problem since most web browsers do not accept a redirection of a HTTPS-based URL. There is no solution for this issue: the standards of HTTP, ICAP and web proxies do not have support for such feature. Basically, this means that blocked HTTPS-based sites cause unexpected error messages like “cannot connect to *site*”.

## 5.7 Main Configuration Settings `ufdbGuard`

Use your favorite editor to edit the configuration file and define which categories must be blocked.

```
$ vi /usr/local/ufdbguard/etc/ufdbGuard.conf
```

There are 5 sections with a comment ‘EDIT THE NEXT LINE’. Find each section and change the configuration where needed.

The first section defines the locations of the log directory and the blacklist database directory. This section does not have to be changed if the initial choice of these locations during the configuration of `ufdbGuard` (see section 4.5) has not changed. The section looks like this:

```
# EDIT THE NEXT LINE FOR LOCAL CONFIGURATION
dbhome /usr/local/ufdbguard/blacklists
logdir /usr/local/ufdbguard/logs
```

The second section defines the IP address range of your local network. The section looks like this:

```
source allSystems {
    ip 10.0.0.0/8
}
```

The appropriate network subnet must be entered in this section. 10.0.0.0/8 and 192.168.0.0/16 are the most common values for this. Consult your network administrator for assistance.

The third section defines the usage and settings of ufdbhttpd, the lightweight http daemon:

```
http-server { port= 8080, interface= all, images="/usr/local/ufdbguard/images" }
```

If you do not use ufdbhttpd, then transform the line above into a comment (with a #).

The fourth and fifth sections are close to each other and define the list of categories to be blocked (one list for the systems with IP address defined in allSystems and one list for all other systems). Change the list of categories to be blocked. The default list of blocked categories contains the categories security, adult, p2p, proxies, gambling, violence and warez. The fourth section looks like this:

```
acl {
    allSystems {
        # EDIT THE NEXT LINE
        pass !adult !p2p !proxies !gambling !violence !warez !security any
    }
}
```

To block a category, it needs to be present with an exclamation mark (!) that is used as a blocking indicator. So to block the *adult* category, !adult must be present in the line that starts with pass. If you prefer to allow gambling, the definition “!gambling” must be removed.

**NOTE:** because of the large set of URLs used by chat applications, configuration of the chat category is a little more complex. See section Error: Reference source not found for a detailed explanation.

At a site that only blocks security, adult, p2p and proxies, the section looks like this:

```
acl {
    allSystems {
        # EDIT THE NEXT LINE
        pass !security !adult !p2p !proxies any
    }
}
```

The fifth section is very similar to the fourth section and defines which categories to block for computer systems that are not part of allSystems.

The configuration for the use of Skype and other chat applications is more complex. Read section 8.7.3 on how to allow or block Skype.

## 5.8 Ensure Access to Internal and 3<sup>rd</sup> Party Websites

The domain name of your company may be included in the URL database of URLfilterDB. To ensure access to all own websites, the category *alwaysallow* should be configured (see section 7.1).

To prevent unhappy users, one should carefully examine which own sites and sites of 3<sup>rd</sup> parties are used for regular daily activities and make sure that these sites can be accessed without restriction. Therefore, it

is recommended to run a few days in test mode (see section 5.11.3) and add sites of important 3<sup>rd</sup> parties to the category *alwaysallow* (see section 7.1).

## 5.9 Redirection Message Variables

A redirect statement may contain variables that are dynamically expanded to their values. E.g. %u is substituted by the URL string that is blocked. So when [www.adult.com](http://www.adult.com) is blocked, the redirection URL

```
http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi?url=%u
```

is dynamically expanded to

```
http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi?url=www.adult.com
```

The variable %u is associated with the parameter *url*. The parameters are interpreted by the URLblocked.cgi script and used to produce an appropriate HTML message for the internet browser of the end user. The following table contains the list of all redirection message parameters.

<i>parameter</i>	<i>variable</i>	<i>explanation</i>
admin	%A	administrator
clientaddr	%a	source address (IP or FQDN)
clientuser	%i	username
clientname	%n	source domainname
clientgroup	%s	source identifier
category targetgroup	%t	URL category
url	%u	URL
url	%U	parsed URL
-	%%	the literal character '%'

*redirection message parameters & variables*

## 5.10 Redirection Message Styles

When a URL is prohibited to be visited, a message is displayed that access is forbidden. The style, size and background color can be set by the administrator.

The options for the background color are: orange (default), white, black, grey and red. The options for the font size of the message are: normal (default), small and large.

To change the style of a message, edit the configuration file and change the default settings of all redirect rules.

```
$ vi /usr/local/ufdbguard/etc/squid.conf
...
redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi?admin=
%A&mode=default&color=orange&size=normal&clientaddr=%a&clientname=%n&clientuser=
%i&clientgroup=%s&targetgroup=%t&url=%u
...
```

Substitute the default value for a new value according to the options specified earlier in this section.

The default error message includes an explanation why the URL is blocked, the URL, the email address of the administrator and a link for more information. Alternatively, the output can be configured to be very

simple and just consist of the word “Forbidden” (in different languages) and the category of the URL in red. To use this style one should set the *mode* parameter to *simple-red*.

The *mode* parameter can have additional values specific for advertisements only. Valid values for *mode* are: transparent (default), noads, square, cross and simple-red. The transparent mode displays nothing, the noads mode displays “no ads”, the square mode shows a grey square, the cross mode shows a transparent cross, and the simple-red mode shows a short message and for ads the text “*ads*”.

The *color* parameter defines the background color and determines automatically an appropriate foreground color. The *size* parameter defines the size of the text.

<i>parameter</i>	<i>value</i>
mode	default noads square cross simple-red
color	white black grey orange red
size	small normal large

*redirection style parameters*

## 5.11 Configure Squid

### 5.11.1 Default configuration

To let Squid use the URL filter (in Squid terminology the URL filter is a *redirector* or a *URL rewriter*), the following 2 parameters must be added to the squid configuration file.

```
$ vi /usr/local/ufdbguard/etc/squid.conf
```

Add the following 2 lines for Squid 2.6 and newer:

```
url_rewrite_program /usr/local/ufdbguard/bin/ufdbgclient -l /usr/local/ufdbguard/logs
url_rewrite_children 64
```

**NOTE:** by default, the ufdguarddd cannot support more than 64 ufdbgclient processes so do not use more than 64 url\_rewrite\_children. Consult the support desk of URLfilterDB in case that you find that the number of URL rewriters is insufficient.

### 5.11.2 Large System Configuration

One systems with a large number of users, the overall system performance can be improved by queueing URL verifications. The implementation of the queueing mechanism of Squid is only suitable for very short queues: ones with a queue depth of 2, 3 or 4, where we prefer a queue depth of 2. In case of errors in the access.log file indicating that all rewriters are busy, one can increase the queue depth.

To configure a queue per URL rewriter, the squid parameter *url\_rewrite\_concurrency* must be set and the *-C* parameter must be used for *ufdbgclient*.

The configuration file of squid must look like this:

```
url_rewrite_program /usr/local/ufdbguard/bin/ufdbgclient -C -l  
/usr/local/ufdbguard/logs  
url_rewrite_concurrency 2
```

### 5.11.3 Test Mode

ufdbGuard has a test mode where internet access is not blocked and where the log file contains lines which web sites would have been blocked in normal mode.

In case that you want to use the test mode, add the `-T` option for `ufdbguardd`. The place to set the options is in `/etc/sysconfig/ufdbguard` on systems that have `/etc/sysconfig` or `/etc/init.d/ufdb` (might be elsewhere for your OS). The file should then have a line like this:

```
UFDB_OPTIONS="-T"
```

In test mode, the log file of `ufdbguardd` contains lines like this:

```
TEST BLOCK adult www.sex.com
```

### 5.11.4 Configuration for 2 servers

In case that `ufdbguardd` runs on a different system than where Squid runs, the server name and port number need to be configured for `ufdbgclient` with the following options:

```
-S servername -p 3977
```

The `squid.conf` file should then have a line like this:

```
url_rewrite_program /local/squid/bin/ufdbgclient -S urlchecker01 -p 3977
```

Also at configuration time, it is required to define the use of 2 servers (see section 4.5.1).

The default port number is 3977 and can be configured to be a different number. To use an alternative port number, one uses the port of choice with the `-p` parameter for the `ufdbgclient` command. To configure an alternative port number for `ufdbguardd`, the keyword `port` followed by the port number is added to its configuration file. In addition, `ufdbguardd` can be configured to use all or one particular interface to listen on. To configure a particular interface, the keyword `interface` must be used in the configuration file. The keyword must be followed by the string "all" or an IP address. By default `ufdbguardd` listens on all interfaces.

Example configuration to listen on port 9999 of interface 10.2.3.4:

```
port 9999  
interface 10.2.3.4
```

## 5.12 Configuration of Browsers

The browsers like Internet Explorer, Firefox, Opera and others need to be configured to

- use the Squid proxy
- display original error messages.

### 5.12.1 Configure Browser to use Squid

How to configure the browser depends much on the chosen technical infrastructure. If Active Directory Server is used, it can be used to configure browsers to use the Squid proxy as the HTTP and HTTPS proxy. Alternative browser can be configured to automatically detect a proxy using the WPAD<sup>1</sup> discovery mechanism or can be configured manually.

---

<sup>1</sup> See for example [http://en.wikipedia.org/wiki/Web\\_Proxy\\_Autodiscovery\\_Protocol](http://en.wikipedia.org/wiki/Web_Proxy_Autodiscovery_Protocol) for more information on WPAD.

### 5.12.2 Configure Internet Explorer to Display Site Error Messages

Internet Explorer of Microsoft has a feature to use an alternative method of displaying HTTP errors which can be confusing because the option ignores any error text produced by a HTTP server and substitutes it by a standard text. It is highly recommended to configure the browser to display the original error messages by *unchecking* the following option:

Internet Options – Advanced – Show friendly HTTP error messages.

### 5.13 Monitoring of ufdbGuard

ufdbGuard uses 2 log files and the system log to write messages to. The location of the log files depends on the choice that was made during the configuration phase (see section 4.5). The names of the log files are `ufdbguardd.log` and `ufdbgclient.log`. The location and name of the system log is OS-dependent and is usually `/var/log/messages` or `/var/adm/syslog.log`.

It is recommended that the log files are regularly inspected, either manually or automatically. Serious errors have a 5-star indicator (\*\*\*\*\*).

### 5.14 Compatibility between ufdbGuard and squidGuard

ufdbGuard 1.0 was based on squidGuard 1.2.0 and a lot has been changed since then. ufdbGuard has new features that squidGuard lacks: *SafeSearch*, *safer HTTPS options*, *logfile rotation*, *HTTP daemon*, *configurable error messages*, *analysis of uncategorised URLs*, and *CPU binding*. ufdbGuard does not support the squidGuard features *user quota*, *ldap*, *mysql* and *separate logfiles*. Despite the differences, a configuration file of squidGuard works with ufdbGuard with little or no modifications.

ufdbGuard uses the more logical keyword `category` where squidGuard uses `destination`. For reasons of compatibility, ufdbGuard recognizes the `destination` keyword.

ufdbGuard has a different database format than squidGuard and has the utility `ufdbConvertDB` to convert the flat files of the database of squidGuard to the database format of ufdbGuard.

### 5.15 Verification of the Configuration

Starting with version 1.29, the configuration file can be verified for errors without starting `ufdbguardd`. There are two ways to verify a configuration file. When the default configuration file is changed, the startup script can be executed with the parameter `configtest`, e.g.:

```
# /etc/init.d/ufdb configtest
```

Alternatively, the `ufdbguardd` program can be called directly to verify the configuration file. Use the normal options as usual and append the command line options “-C verify”, e.g.:

```
# ufdbguardd -c new.conf -C verify
```

## 6 Start the URL Filter

To start the URL filter daemon:

```
# /etc/init.d/ufdb start
```

Now you can restart squid to use the URL filter:

```
# /etc/init.d/squid reload
```

or

```
# /etc/init.d/squid stop
```

```
# /etc/init.d/squid start
```

## 7 Exception Rules

In cases where exceptions to the categories of URLfilterDB are desired, an administrator can define 2 extra categories that are managed by the administrator and never by URLfilterDB.

### 7.1 Allow Extra Sites

A common case is that you want to ensure access to your own websites and websites of 3<sup>rd</sup> parties that are used for normal activities. To grant users access to the company websites, the URL `yourcompany.com` needs to be added to the category *alwaysallow*.

For universities that want to allow access to all other universities in the United States, a simple `edu` in the *alwaysallow* list. In the UK, only `ac.uk` needs to be included!

Edit the file that contains the extra sites that should always be allowed:

```
$ cd /usr/local/ufdbguard
$ vi blacklists/alwaysallow/domains
```

Add the appropriate URLs and always remove a leading www.:

```
yourcompany.com
news.google.com
google.com/news
```

In case that you have a file with many URLs having a leading `www.`, you may use the `-W` option to remove the `www.` prefix automatically.

Additional domains can be added according to the local internet usage policy. For example, if news should be blocked but access to CNN allowed, then `cnn.com` should be added also. Alternatively, when news should be blocked but Google news allowed, `news.google.com` and `google.com/news` should be added.

ufdbGuard only uses proprietary database files, so generate an `.ufdb` database file from the ASCII file with `ufdbGenTable`:

```
$ cd /usr/local/ufdbguard
$ bin/ufdbGenTable -W -n -t alwaysallow -d blacklists/alwaysallow/domains
```

The above command generates the file `blacklists/alwaysallow/domains.ufdb` and should be invoked each time that the domains file is changed. `ufdbGenTable` has a sanity check option (`-s`) which performs a few checks on the validity of the URLs. It is recommended to use this option. The `-W` option removes the initial `www.` from all URLs.

Then activate the category by editing the `ufdbGuard.conf` file and uncomment the category definition for *alwaysallow*. The configuration file should have the following lines:

```
category alwaysallow
{
    domainlist alwaysallow/domains
    redirect ...
}
```

Also add the category *alwaysallow* to the ACL `allSystems`. The ACL should then start with

```
pass alwaysallow !adult ...
```

Finally signal the `ufdbguardd` daemon about the new configuration:

```
# /etc/init.d/ufdb reconfig
```

## 7.2 Block Extra Sites

In case that you want to block access to a site that is not in any category, you can add this site to the category *alwaysdeny*. For example, `google.com` is not in any category but if you like to block access to this popular search engine, `google.com` can be included in the *alwaysdeny* category. Analogous to the *alwaysallow* category, the domain (without leading `www.`) must be added to the category `domains` file, and the ACL `allSystems` must be extended.

Edit the file that contains the extra sites that should always be blocked:

```
$ cd /usr/local/ufdbguard
$ vi blacklists/alwaysdeny/domains
```

Add the appropriate URLs (always remove a leading `www.`):

```
google.com
```

`ufdbGuard` only uses proprietary database files, so generate an `.ufdb` file from the ASCII file with `ufdbGenTable`:

```
$ cd /usr/local/ufdbguard
$ bin/ufdbGenTable -W -n -t alwaysdeny -d blacklists/alwaysdeny/domains
```

The `-W` option removes the initial `www.` from all URLs. The above command generates the file `blacklists/alwaysdeny/domains.ufdb` and should be invoked each time when the `domains` file is changed. Then activate the category by editing the `ufdbGuard.conf` file and uncomment the category definition for *alwaysdeny*. The configuration file should have the following lines:

```
category alwaysdeny
{
    domainlist alwaysdeny/domains
    redirect ...
}
```

Also, add the category *alwaysdeny* to the ACL `allSystems`. The ACL should then start with

```
pass alwaysallow !alwaysdeny !adult ...
```

Finally signal the `ufdbguardd` daemon about the new configuration:

```
# /etc/init.d/ufdb reconfig
```

## 7.3 Block Extra Sites – a more Advanced Example

If *parts* of a website need to be blocked, the method described in the previous section does not provide a solution. Suppose we allow users to watch CNN news but do not want them to look at the CNN news videos.

It was observed that the CNN videos are made available through the following URLs:

```
http://www.cnn.com/video
http://edition.cnn.com/video
http://vid.cnn.com
```

Since access to `www.cnn.com` is allowed and access to `www.cnn.com/video` is not, a *domain block* is not an option, but a so-called *url block* is. Therefore, in this example the above URLs need to be divided into 2 categories: those which can be blocked with domain blocks and those which can be blocked with url blocks.

The block referring to a domain goes into the file `.../alwaysdeny/domains`:

vid.cnn.com

and the blocks referring to a full URL go into the file `.../alwaysdeny/urls`:

`cnn.com/video`<sup>2</sup>

`edition.cnn.com/video`

The `ufdbGenTable` command has a `-u` option to include the url blocks and the command to generate a new `.ufdb` file including all options becomes this:

```
$ cd /usr/local/ufdbguard/blacklists
```

```
$ ../bin/ufdbGenTable -W -n -t alwaysdeny -d alwaysdeny/domains -u alwaysdeny/urls
```

Do not forget to signal the `ufdbguardd` daemon about the new configuration:

```
# /etc/init.d/ufdb reconfig
```

## 8 Advanced Options

### 8.1 Blocking Adult Images produced by Search Engines

Search engines like Google, Yahoo and MSN have a capability to search for images and allow users to view adult images that can not be blocked in a simple way since the images come from Google, Yahoo and MSN themselves and in general one would not like to block all images from the search engines.

Google<sup>3</sup>, Yahoo and other search engines offer a *SafeSearch*<sup>TM</sup> feature which blocks most adult images. `UfdbGuard` has the configuration parameter `safe-search` that enforces the safesearch policies of the search engines. The default value for the parameter is `ON`.

The safesearch feature enforces safe searches for the following search engines: A9, AOL search, Alltheweb, Ask, Bing, Blinkx, Buscamundo, Dogpile, Excite, Foxnews, Google, Infospace, Live, Lycos, Metacrawler, Metaspy, MSN, Terra, Webcrawler, webpile, Yahoo and other less popular search engines.

#### 8.1.1 SafeSearch of Google

Google allows users to search using HTTP and HTTPS. Searches with HTTP can be modified by a URL filter to force a SafeSearch but searches with HTTPS are not modifiable. Google therefore recommends to do the following to ensure that content filters are able to enforce SafeSearch.

1. block `encrypted.google.com`
2. configure the DNS entry for `www.google.com` to be a CNAME for `nossllsearch.google.com`.

#### 8.1.2 Global SafeSearch Option

To enforce SafeSearch for all users, use

```
safe-search on
```

#### 8.1.3 Per-ACL SafeSearch Option

To have fine-grained control over the SafeSearch feature, the global `safe-search` feature must be turned off and a category must be defined that includes the `safe-search` option. The newly created category can be used in the ACLs as demonstrated in the following example.

```
safe-search off
```

```
...
```

---

<sup>2</sup> Note that there is no leading `www.` since the URL filter works internally with stripped URLs that do not contain a `www.` part. Use the `-W` option for files with URLs that have a `www.` prefix.

<sup>3</sup> Google SafeSearch filtering is a trademark of Google.

```
category safesearch {
    option safe-search on
}
...
acl {
    ...
    allSystems {
        pass !alwaysdeny !proxies ... !safesearch any
    }
}
```

## 8.2 YouTube Education Filter

YouTube has a filter for schools. Details about the filter are on the help system of YouTube: <http://support.google.com/youtube/bin/answer.py?hl=en&answer=1686318>. To be able to use the educational filter of YouTube one must setup a school account and request an edufilter ID.

The use of the YouTube educational filter is controlled with two parameters:

```
youtube-edufilter      on
youtube-edufilter-id  "ABCD1234567890abcdef"
```

## 8.3 Different Policies for Different Users

Suppose that ufdbGuard is used in a bank. The internet usage policy could be defined as: block sex, chat, dating, entertainment, finance, news, webmail. This policy can be appropriate for most users but not for staff working in a dealing room where access to news and finance-related sites is required. This section explains how to achieve this.

Always be careful with the order of rules and make sure that the more privileged user (groups) is defined first in the ACL.

### 8.3.1 Policy based on IP Address

If the dealing room has a separate IP subnet, the *dealing room* policy can be defined in the following way in the ufdbGuard configuration file.

```
source dealingroom {
    ip 10.4.0.0/16      # e.g. the dealing room uses this subnet
}

acl {
    # more privileged users first
    dealingroom {
        pass !security !adult !warez any
    }
    allSystems {
        pass !security !adult !p2p !proxies !dating !entertain !warez any
    }
    default {
        pass none
        # the following redirect is for the pseudo category 'none'
        redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?...
    }
}
```

## 8.3.2 Policy based on Username

Internet access policies can also be based on an individual user or a list of usernames. In this example, a list of usernames is used to use the dealingroom policy. The source definition defines which users are members of the group *dealingroom*.

```
source dealingroom {
    user      "admin"
    userlist  "/usr/local/ufdb/etc/dealers"
}
```

The file `/usr/local/ufdb/etc/dealers` should contain the usernames of all dealers. The final policy definition is the same as a policy based on IP address:

```
acl {
    # more privileged users first
    dealingroom {
        pass !security !adult !proxies !dating any
    }
    allSystems {
        pass !security !adult !proxies !chat !dating !entertain !webmail any
    }
    default {
        pass none
        redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?...
    }
}
```

**CAVEAT:** additional configuration is required to make Squid able to find out which users are using Squid. You may configure Squid to use user authentication *or* you have to install `identd` on all PCs to support this feature. Please read the Squid documentation for more information and do not forget to use `acl foo ident REQUIRED`.

## 8.3.3 Usernames with Domainnames

In case that users are authenticated by Squid, squid sends the authenticated username to `ufdbGuard`. The authenticated username can include a domainname, e.g. "johndoe@MYDOMAIN". To be able to match usernames with an included domainname, `ufdbGuard` has a new<sup>4</sup> option `strip-domain-from-username`. This option is `off` by default, and should be turned on when applicable.

### *Example of LDAP authentication*

Let's assume that users are authenticated by Squid using LDAP. The PAM LDAP module (see also `man pam_ldap`) should be configured and `ufdbGuard` should have an appropriate source definition. E.g.

```
source managers {
    unix group "managers"
}
source staff {
    unix group "staff"
}
```

where `managers` and `staff` are LDAP groups.

---

<sup>4</sup> the option `strip-domain-from-username` was introduced in version 1.29.

Note that starting with v1.30 there is an alternative way to use LDAP-based groups. See section 8.3.5 for more information.

### 8.3.4 Policy based on UNIX Group name

Internet access policies can also be based on a UNIX group. In this example, a groupname is used to use the dealingroom policy. In this case, the `source` definition defines that the group `dealer` represents the dealingroom.

```
source dealingroom {
    unix group dealer
}
```

The group `dealer` must be a valid UNIX group name. The final policy definition is the same as a policy based on IP address:

```
acl {
    # more privileged users first
    dealingroom {
        pass !security !adult !proxies !dating any
    }
    allSystems {
        pass !security !adult !proxies !chat !dating !entertain !webmail any
    }
    default {
        pass none
        redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?...
    }
}
```

**CAVEAT:** additional configuration is required to make Squid able to find out which users are using Squid. You may configure squid to use user authentication or you have to install `identd` on all PCs to support this feature. Please read the Squid documentation for more information and do not forget to use `acl foo ident REQUIRED`.

### 8.3.5 Policy based on Dynamically Generated List of Usernames

`ufdbguard` can import lists of users from any user database, whether it is LDAP, Kerberos-based, Active Directory, MySQL or any other type of database with usernames. The database is queried using an external script that produces a list of usernames, one username per line. `ufdbguardd` regularly executes the external script to always be up-to-date.

Internet access policies can be based on dynamically generated list of usernames. In this example, a list of usernames is used to use the finance policy. The `source` definition defines which users are members of the group *finance*.

```
source finance {
    execuserlist "/usr/local/ufdb/bin/execuserlist.sh finance"
}
```

The user-defined shell script `/usr/local/ufdb/bin/execuserlist.sh` must produce a list of usernames, one per line. An example shell script `execuserlist.sh` is located in the `.../samples` directory. The example script uses `ldapsearch` to produce a list of usernames based on a OU in a n example LDAP database and can be adapted to produce a list of users based on any type of user directory that can be queried from the command line.

`execuserlist` must be followed by a quoted command which may include parameters.

The command defined by each `execuserlist` is executed when `ufdbguardd` starts and also every 15 minutes to automatically pick up changes in user groups.

The final policy definition is the same as a policy based on IP address:

```
acl {
    # more privileged users first
    finance {
        pass !security !adult !proxies any
    }
    allSystems {
        pass !security !adult !proxies !chat !dating !entertain !webmail any
    }
    default {
        pass none
        redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?...
    }
}
```

**CAVEAT:** additional configuration is required to make Squid able to find out which users are using Squid. You may configure Squid to use user authentication *or* you have to install `identd` on all PCs to support this feature. Please read the Squid documentation for more information and do not forget to use `acl foo ident REQUIRED`.

The list of usernames retrieved by `execuserlist` is retrieved again every 15 minutes to automatically pick up changes in user groups. The refresh time (default 15 minutes) can be set using the `refreshuserlist` keyword followed by a number representing the number of minutes for the refresh interval. The interval must be between 5 and 1440 minutes. For example:

```
refreshuserlist 5
```

Debugging scripts which generates a list of usernames may be difficult and therefore `ufdbguardd` has an option to debug and log the output generated by shell scripts. For example:

```
ufdb-debug-external-scripts on
```

The logfile of `ufdbguardd` will contain lines with `execuserlist: received "foo"` when the debug option is on.

### 8.3.6 Policy based on Domain Name

Internet access policies can also be based on the domain name of a PC. In this example, the PCs in the dealingroom have a unique domain name that can be used to define a policy.

Let's assume that the dealingroom PCs have a name with the same subdomain like `pc31.dealingroom.bank.com`, and then the source definition for the dealingroom group is as follows:

```
source dealingroom {
    domain "dealingroom.bank.com"
}
```

**NOTE:** To use this feature, the reverse name lookup must be enabled in `squid.conf`:

```
log_fqdn on
```

## 8.4 Multiple ACLs

In case that there are exceptions for (groups) of users, multiple ACLs will be used (see also the examples for a dealing room in the previous sections).

The order of the definition of sources is important since the *first* source that matches a URL/user/IP is used to determine a block or a pass and no further sources are taken into account. The following example demonstrates this.

Suppose there is an administration PC that should have access to all websites and that the PC has a fixed IP address: 10.2.3.4. The configuration file should have the source definition for the administration PC *in front of* the source allSystems. Otherwise, the administration PC is considered part of allSystems and the ACL rule for adminpc is never used to decide a block or pass. So the order of the definitions is always important.

```
source adminpc {
    ip 10.2.3.4
}
source allSystems {
    ip 10.0.0.0/8
}
acl {
    adminpc {
        pass any
    }
    allSystems {
        pass !security !adult !proxies !chat !dating !entertain !webmail any
    }
    default {
        pass none
        redirect http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?...
    }
}
```

Note that the `redirect` statement is required because the pseudo-category `none` is used.

## 8.5 Time-Based ACLs

ufdbGuard supports time-based ACLs which enable the implementation of internet usage policies that have different policies during different time of the day or week. As the first step, a definition of one or more time intervals is given with the `time` statement. A time interval definition can contain two types of time intervals: the `weekly` directive is used to define reoccurring time intervals and the `date` directive is used to define special dates. The syntax is explained with the following example.

```
time "working-hours" {
    weekly mon,tue,wed,thu,fri 08:00 - 19:00
    weekly sat,sun             08:00 - 12:30
    date  *-*-01    # every first of the month
    date  2010-12-31
}
```

Weekly reoccurring hours have one or more days separated by commas or a wild character, followed by a time interval: `HH:MM - HH:MM`. The names of the days may be replaced by the wild card "\*" to denote all days. Dates have the format `YYYY-MM-DD` and may contain a wild character for the year, month and/or day.

Once the time intervals are defined, they can be applied to the ACLs with the directives `within`, `outside` and `else`. The following example shows how these directives can be used.

```
acl {
    allSystems within "working-hours" {
        pass !security !adult !proxies !p2p !dating !entertain !webmail any
    } else {
        pass !security !adult !proxies !p2p any
    }
    ...
}
```

In the above example users are not allowed access to sites in the categories dating, entertainment and webmail during office hours. The `else` part defines an alternative ACL for all other hours that are not inside the *working-hours* time interval. The `else` part is optional.

As an alternative to the `within` directive, the `outside` directive can be used which has opposite semantics.

## 8.6 Whitelisting

Whitelisting is used in case that users are only allowed to visit a predefined set of websites. In this case, the ACL for `allSystems` contains the categories *alwaysallow* and *none*. The ACL in the configuration file looks like this:

```
acl {
    allSystems {
        pass alwaysallow none
        # the following redirect is for the pseudo category 'none'
        redirect "http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?..."
    }
    default {
        pass none
        redirect "http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.pl?..."
    }
}
```

Note that the extra `redirect` statement is required because the pseudo-category *none* is used.

## 8.7 Chat Applications

Many chat applications have more functionality than a simple chat. They can share files or even do remote control of another workstation. These additional features bring security risks and may violate the local Internet Usage Policy. It is suggested to evaluate the use of ebuddy (see <http://www.ebuddy.com>) since this chat application can connect to all major chat sites but does not have the additional features.

In case that one or more chat applications are allowed, the ACL to configure this requirement is a little more complex because the chat applications use a large and complex set of URLs and most chat applications use the HTTPS port for a proprietary protocol which may violate HTTPS security options. The next sections describe in detail on how to block or allow one or more chat applications.

It is possible to block or allow a subset of chat applications, but since the chat applications use a large set of URLs and use login server, chat servers and direct peer to peer communication, both over HTTP and HTTPS, the ACLs for correct and efficient implementation of the requirements are different than other URL categories. This section explains the details and it is recommended to read the whole section to understand all aspects.

## 8.7.1 Chat and HTTPS

Many chat protocols use the HTTPS port. Many chat protocols use a proprietary protocol and hence not the normal SSL encrypted data stream that the normal HTTPS websites use. ufdbGuard, however, has important security features to detect SSH tunnels and other proxies and VPNs over HTTPS and probes HTTPS ports to detect them.

To enable chat applications *and* to detect tunnels and proxies correctly, there are rules for the ACLs as explained in the following sections.

## 8.7.2 Ebuddy

Ebuddy is a web-based chat application that provides chat, voice and video calls. Ebuddy does not have additional features like file sharing that may violate a local Internet Usage Policy and is therefore considered safer than other chat and VOIP applications.

Blocking Ebuddy is easy because one only needs to block a small set of URLs to block the whole application. To block Ebuddy, the subcategory `chat-ebuddy` must be defined and the relevant ACL must contain `!chat-ebuddy` to block Ebuddy.

The URL database has a subcategory for ebuddy called `chat-ebuddy`. The default definition is as follows:

```
category chat-ebuddy {
    domainlist      "chat/ebuddy/domains"
    expressionlist  "chat/ebuddy/expressions"
    redirect        ...
}
```

To allow ebuddy chat, the ACL must include the `chat-ebuddy` category in front of the `security` and `proxies` category. The ACL must be similar to the following:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-ebuddy
        !security !proxies ...
    }
    ...
}
```

## 8.7.3 Skype

Skype is a VOIP application that also can be used to transfer files and give remote access using screen sharing. These additional features *may* violate the local Internet Usage Policy.

Blocking Skype is easy because one only needs to block a small set of URLs to block the whole application. To block Skype, the subcategory `chat-skype` must be defined and the relevant ACL must contain `!chat-skype` to block Skype.

Skype is a popular VOIP application that requires a more complex configuration because it uses the HTTPS port 443 for its proprietary protocol, which would be blocked if the options for safer HTTPS are used. Skype also uses IP addresses instead of hostnames, so Skype conflicts with the security options `enforce-https-with-hostname` and `enforce-https-official-certificate`. The URL database of URLfilterDB contains a subcategory for Skype with many URLs that Skype uses. Since Skype connects to IP addresses of Skype users, it is not feasible to have all these IP addresses in the URL database and therefore ufdbGuard dynamically detects the use of Skype.

An extra subcategory needs to be configured:

```
category chat-skype {
    domainlist      "chat/skype/domains"
    expressionlist  "chat/skype/expressions"
    redirect        ...
}
```

For those who want to use Skype and have a safer use of HTTPS, a new option has been introduced in version 1.23: `allow-skype-over-https`. The category `security` must have this option set to ON:

```
category security {
    option          allow-skype-over-https on
    ...
}
```

**Note:** URLs are matched against categories in the order that they appear in an ACL and therefore the category `chat-skype` must be placed *before* the categories `security` and `proxies` in the ACLs to prevent that the security category blocks access to Skype URLs, e.g.:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-skype
        !security !proxies ...
    }
    ...
}
```

Skype must be configured to use Squid as its proxy: menu Options, tab Advanced, tab Connection, HTTPS proxy.

## 8.7.4 Yahoo Messenger

Yahoo instant messenger, or Yahoo IM, is a chat and VOIP application that also can be used to transfer files. These additional features *may* violate the local Internet Usage Policy.

Blocking Yahoo IM is easy because one only needs to block a small set of URLs to block the whole application. To block Yahoo IM, the subcategory `chat-yahoo` must be defined and the relevant ACL must contain `!chat-yahoo` to block Yahoo IM.

Yahoo IM is a popular chat application that requires a more complex configuration because it uses the HTTPS port 443 for its proprietary protocol, which would be blocked if the options for safer HTTPS are used. Yahoo IM also uses IP addresses instead of hostnames, so Yahoo IM conflicts with the security options `enforce-https-with-hostname` and `enforce-https-official-certificate`. The URL database of URLfilterDB contains a subcategory for Yahoo IM with many URLs that Yahoo IM uses. Since Yahoo IM connects to a large set of IP addresses, it is impossible to have all these IP addresses in the URL database and therefore `ufdbGuard` dynamically detects the use of Yahoo IM.

Yahoo IM also uses URLs which are used by other services of Yahoo. These other services may be blocked by the configuration which is a potential problem. Therefore there is a second subcategory called `chat-allowed` which contains these URLs. This subcategory contains only a few URLs and should be placed in an ACL immediately following `chat-yahoo`.

The two subcategories are in the default configuration file `ufdbGuard.conf` of version 1.25 or later but inside comments. The default definition of the subcategories is:

```
category chat-yahoo {
    domainlist      "chat/yahoo/domains"
    expressionlist  "chat/yahoo/expressions"
    redirect        ...
}
category chat-allowed {
    domainlist      "chat/allowed/domains"
    expressionlist  "chat/allowed/expressions"
    redirect        ...
}
```

And the security category must have the following option settings:

```
category security {
    option          allow-yahoomsg-over-https on
    ...
}
```

**Note:** URLs are matched against categories in the order that they appear in an ACL and therefore the category chat-yahoo must be placed *before* the categories security and proxies in the ACLs to prevent that the security category blocks access to Yahoo IM URLs, e.g.:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-yahoo chat-allowed
        !security !proxies ...
    }
    ...
}
```

Yahoo IM must be configured to use Squid as its proxy: menu Messenger, item Preferences, category Connection, option connect via a proxy server, option HTTP proxy.

## 8.7.5 Facebook Chat

Facebook Chat is a chat and VOIP application. Blocking Facebook Chat is easy because one only needs to block a small set of URLs to block the whole application. To block Facebook Chat, the subcategory chat-facebook must be defined and the relevant ACL must contain !chat-facebook to block Facebook Chat.

Facebook Chat is a popular chat application that requires a more complex configuration because it uses the HTTPS port 443 for its VOIP protocol, which would be blocked if the options for safer HTTPS are used. Facebook Chat also uses IP addresses instead of hostnames, so Facebook Chat conflicts with the security options enforce-https-with-hostname and enforce-https-official-certificate. The URL database of URLfilterDB contains a subcategory for Facebook Chat with many URLs that Facebook Chat uses. Since Facebook Chat connects to a set of IP addresses, it is impossible to have all these IP addresses in the URL database and therefore ufdbGuard dynamically detects the use of Facebook Chat.

Facebook Chat also uses URLs which are used by other services of Facebook. These other services may be blocked by the configuration which is a potential problem. Therefore there is a second subcategory called chat-allowed which contains these URLs. This subcategory contains only a few URLs and should be placed in an ACL immediately following chat-facebook.

The two subcategories are in the default configuration file `ufdbGuard.conf` of version 1.27 or later but inside comments. The default definition of the subcategories is:

```
category chat-facebook {
    domainlist      "chat/facebook/domains"
    expressionlist  "chat/facebook/expressions"
    redirect        ...
}
category chat-allowed {
    domainlist      "chat/allowed/domains"
    expressionlist  "chat/allowed/expressions"
    redirect        ...
}
```

And the security category must have the following option settings:

```
category security {
    option          allow-fb-chat-over-https on
    ...
}
```

**Note:** URLs are matched against categories in the order that they appear in an ACL and therefore the category `chat-facebook` must be placed *before* the categories `security` and `proxies` in the ACLs to prevent that the security category blocks access to Facebook Chat URLs, e.g.:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-facebook chat-allowed
        !security !proxies ...
    }
    ...
}
```

### 8.7.6 AOL Messenger

AOL instant messenger, or AIM, is a chat and VOIP application that also can be used to transfer files. These additional features *may* violate the local Internet Usage Policy.

Blocking AIM is easy because one only needs to block a small set of URLs to block the whole application. To block AIM, the subcategory `chat-aim` must be defined and the relevant ACL must contain `! chat-aim` to block AIM.

AIM is a popular chat application that requires a more complex configuration because it uses the HTTPS port 443 for its proprietary protocol, which would be blocked if the options for safer HTTPS are used. AIM sometimes also uses IP addresses instead of hostnames, so AIM conflicts with the security options `enforce-https-with-hostname` and `enforce-https-official-certificate`. The URL database of URLfilterDB contains a subcategory for AIM with many URLs that AIM uses. Since AIM connects to a large set of IP addresses, it is impossible to have all these IP addresses in the URL database and therefore `ufdbGuard` dynamically detects the use of AIM.

AIM also uses URLs which are used by other services of AOL. These other services may be blocked by the configuration which is a potential problem. Therefore there is a second subcategory called `chat-`

allowed which contains these URLs. This subcategory contains only a few URLs and should be placed in an ACL immediately following chat-aim.

The two subcategories are in the default configuration file ufdbGuard.conf of version 1.25 or later but inside comments. The default definition of the subcategories is:

```
category chat-aim {
    domainlist      "chat/aim/domains"
    expressionlist  "chat/aim/expressions"
    redirect        ...
}
category chat-allowed {
    domainlist      "chat/allowed/domains"
    expressionlist  "chat/allowed/expressions"
    redirect        ...
}
```

And the security category must have the following option settings:

```
category security {
    option          allow-aim-over-https on
    ...
}
```

**Note:** URLs are matched against categories in the order that they appear in an ACL and therefore the category chat-aim must be placed *before* the categories security and proxies in the ACLs to prevent that the security category blocks access to AIM URLs, e.g.:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-aim chat-allowed
        !security !proxies ...
    }
    ...
}
```

AIM must be configured to use Squid as its proxy: menu Menu, item Settings, category Connection, option connect using proxy and protocol HTTP/HTTPS.

## 8.7.7 Google Talk

Google Talk is a chat and VOIP application that also can be used to transfer files. This additional feature *may* violate the local Internet Usage Policy.

Blocking Google Talk is easy because one only needs to block a small set of URLs to block the whole application. To block Google Talk, the subcategory chat-google must be defined and the relevant ACL must contain !chat-google to block Google Talk.

Google Talk is a popular VOIP application that requires a more complex configuration because it uses the HTTPS port 443 for its proprietary protocol, which would be blocked if the options for safer HTTPS are used. Google Talk also uses IP addresses instead of hostnames, so Google Talk conflicts with the security options enforce-https-with-hostname and enforce-https-official-certificate. The URL database of URLfilterDB contains a subcategory for Google Talk with many URLs that Google

Talk uses. Since Google Talk connects to a large set of IP addresses, it is impossible to have all these IP addresses in the URL database and therefore ufdbGuard dynamically detects the use of Google Talk.

To allow Google Talk the following subcategories are used:

```
category chat-google {
    domainlist      "chat/google/domains"
    expressionlist  "chat/google/expressions"
    redirect        ...
}
category chat-allowed {
    domainlist      "chat/allowed/domains"
    expressionlist  "chat/allowed/expressions"
    redirect        ...
}
```

And the security category must have the following option settings:

```
category security {
    option          allow-gtalk-over-https on
    ...
}
```

**Note:** URLs are matched against categories in the order that they appear in an ACL and therefore the category `chat-google` must be placed *before* the categories `security` and `proxies` in the ACLs to prevent that the security category blocks access to Google Talk URLs, e.g.:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-google chat-allowed
        !security !proxies ...
    }
    ...
}
```

Google Talk must be configured to use Squid as its proxy: menu Settings, category Connection, option Use the following proxy.

### 8.7.8 Live Messenger - MSN

Live Messenger, a.k.a. MSN, is a chat and VOIP application that also can be used to transfer files. This additional feature *may* violate the local Internet Usage Policy.

Blocking MSN is easy because one only needs to block a small set of URLs to block the whole application. To block MSN, the subcategory `chat-msn` must be defined and the relevant ACL must contain `!chat-msn` to block MSN.

MSN is a popular VOIP application that requires a more complex configuration because it uses a large set of URLs and some URLs are used for other purposes than only chat.

**Note:** MSN clients also communicate directly with `login.live.com` on port 443 and therefore firewalls rules need to be set. This behavior is at least *odd* and MSN messenger should use the proxy for all traffic but this is not the case.

To allow MSN the following subcategories are used:

```
category chat-msn {
    domainlist      "chat/msn/domains"
    expressionlist  "chat/msn/expressions"
    redirect        ...
}
category chat-allowed {
    domainlist      "chat/allowed/domains"
    expressionlist  "chat/allowed/expressions"
    redirect        ...
}
```

**Note:** URLs are matched against categories in the order that they appear in an ACL and therefore the category `chat-msn` must be placed *before* the categories `security` and `proxies` in the ACLs to prevent that the `security` category blocks access to MSN URLs, e.g.:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat-msn chat-allowed
        !security !proxies ...
    }
    ...
}
```

MSN must be configured to use Squid as its proxy: menu Tools, item Options, category Connection, Advanced Settings, HTTP proxy server.

## 8.7.9 All chat applications

Skype and other chat application can also be used to transfer files and give remote access using screen sharing. These additional features may violate the local Internet Usage Policy.

Blocking all chat is relatively easy because one only needs to block a small set of URLs to block the chat applications. To block all chat, the URL category `chat` must be defined and the relevant ACL must contain `!chat` to block all chat and set the relevant options in the `security` category OFF.

```
category security {
    option      allow-aim-over-https off
    option      allow-gtalk-over-https off
    option      allow-skype-over-https off
    option      allow-yahoomsg-over-https off
    ...
}
```

To allow all chat applications, the ACL must have the `chat` and `chat-allowed` categories in front of the `security` and `proxies` categories and the `security` category must have the correct settings for options that control the behaviour of `ufdbguardd` for HTTPS ports (port 443).

The default configuration file of `ufdbguardd` version 1.25 and higher have the following URL categories defined.

```
category chat {
    domainlist      "chat/domains"
    expressionlist  "chat/expressions"
    redirect        ...
}
category chat-allowed {
    domainlist      "chat/allowed/domains"
    expressionlist  "chat/allowed/expressions"
    redirect        ...
}
```

The ACL to allow all chat applications is as follows:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        chat chat-allowed
        !security !proxies ...
    }
    ...
}
```

Various chat applications use the HTTPS port (port 443) but do not use URLs with a FQDN and do not use SSL. Therefore the security category must have the following options set.

```
category security {
    option          allow-aim-over-https on
    option          allow-gtalk-over-https on
    option          allow-skype-over-https on
    option          allow-yahoomsg-over-https on
    option          allow-unknown-protocol-over-https on
    ...
}
```

## 8.8 Anti-phishing from PhishTank

PhishTank ([www.phishtank.com](http://www.phishtank.com)) provides a URL list with URLs used for phishing. Starting with version 1.29, ufdbGuard downloads an up-to-date version of the URL list from PhishTank. Users of ufdbGuard can choose to include this URL list in the access control list.

URLfilterDB and PhishTank are not associated in any way and the URL list of PhishTank is not part of the URL database of URLfilterDB. The URL list of PhishTank is always downloaded independently on the system where ufdbUpdate is executed.

To use the URL list of PhishTank, the configuration file should include the definition of the URL category, e.g.

```
category phishtank {
    domainlist      "phishtank/domains"
    expressionlist  "phishtank/expressions"
    redirect        ...
}
```

The ACL to block URLs of the phishtank category is as follows:

```
acl {
    allSystems {
        pass alwaysallow !alwaysblock
        !phishtank
        !security !proxies ...
    }
}
```

In case that the URL list of PhishTank is not desired and must be prevented to be downloaded, the configuration file `ufdbGuard.conf` must contain the following line.

```
# do-not-download-phishtank
```

Alternatively, to prevent downloads of the URL list of PhishTank, an empty file with the name `.nodownloads` in the directory `.../phishtank` prevents downloads.

## 8.9 Default blocking behavior

### 8.9.1 ufdbguardd

The URL filtering system has two conditions where it cannot perform the regular filtering function:

- a) whenever there is a fatal error
- b) when the URL database is reloaded.

By default, whenever one of the 2 conditions occur, `ufdbguardd` sends a message to Squid telling Squid that the URL is not filtered, i.e. allowed to see. The only possible alternative to allowing all URLs, is to block all URLs. For those environments where it is necessary to block all URLs under the above conditions, the following 2 configuration settings can be set in the configuration file:

```
url-lookup-result-during-database-reload    deny
url-lookup-result-when-fatal-error          deny
```

When any of the above two parameters is set to “deny”, browsers are redirected and display an appropriate message. To overrule the default messages one can configure URLs that point to web pages to display own messages for fatal errors and when it is loading a database with the following two parameters.

```
redirect-fatal-error      "http://www.example.com/fatalerror.html"
redirect-loading-database "http://www.example.com/loadingdb.html"
```

### 8.9.2 ufdbgclient

`ufdbgclient` is the glue between Squid and `ufdbguardd`. By default, when `ufdbgclient` cannot communicate with `ufdbguardd`, it allows all URLs, i.e. all URL filter requests of Squid are answered with a message indicating that the URL is allowed. The only possible alternative to allowing all URLs is to block all URLs. To block all URLs when `ufdbguardd` is not running or there is a fatal communication error, `ufdbgclient` can be started with the “`-e deny`” option.

In case of a fatal error, `ufdbgclient` returns by default the URL <http://cgibin.urlfilterdb.com/cgi-bin/URLblocked.cgi?category=fatal-error> which displays an appropriate message. To overrule the default redirection URL for fatal errors, the `-E` option can be used which takes a valid URL as its argument, e.g. `-E http://example.com/error.html`

The `-e` and `-E` options must be specified in the configuration file of Squid, `squid.conf`. E.g.:

```
url_rewrite_program /local/squid/bin/ufdbgclient -e deny
```

## 8.10 Extended Logging

ufdbGuard has 3 options for extended logging. The keyword `logblock` followed by `on` or `off` tells ufdbGuard whether to register blocked URLs in its logfile. The keyword `logall` followed by `on` or `off` tells ufdbGuard whether to register *all* URL verifications in its logfile. The keyword `logpass` followed by `on` or `off` tells ufdbGuard to log explicitly allowed URL categories.

`logpass` was introduced in v1.29 to log explicitly allowed URL categories. The most obvious example of such URL category is *always-allowed*. One can also define more explicitly allowed URL categories. For example, if a site allows webmail but likes to monitor the use of webmail, it can explicitly allow webmail in the ACL and use `logpass` to log its use. An ACL for this example looks like this:

```
acl {
    allSystems {
        pass always-allow !always-block !proxies !adult webmail any
    }
    ...
}
```

Warning: `logall on` requires many resources and has a performance impact on ufdbGuard.

## 8.11 Logfile Rotation

ufdbGuard rotates its logfile automatically whenever it grows beyond 200 MB. When the logfile is rotated, the file `ufdbguarddd.log` to `ufdbguarddd.log.1` and recreates `ufdbguarddd.log`. A maximum of 8 log files are kept. Note that with the default size of 200 MB, hence the file system where ufdbGuard is installed needs 1.6 GB free space for the log files.

On receipt of the USR1 signal, ufdbguarddd also rotates the logfile. The most convenient way to do this is to use `/etc/init.d/ufdb rotatelog`, which takes care of sending the USR1 signal to the right process.

The maximum logfile size is configurable with a parameter in the configuration file. The following line sets the maximum size to 50 MB.

```
max-logfile-size 50000000
```

## 8.12 Using Quotes

ufdbGuard has many reserved words that cannot be used as labels without using double quotes. In case that you have the need to use a source or category name that is identical to a reserved word, you may use it surrounded by double quotes. E.g.

```
category "aggressive" {

source "unix" {

pass ... !"aggressive" ...
```

Also file names, URL redirection strings, ACLs and parameters `dbhome` and `logdir` accept quoted parameters. E.g.

```
logdir "/usr/local/ufdbguard"
time "working-hours" {

category "aggressive" {
    domainlist      "aggressive/domains"
    expressionlist  "aggressive/expressions"
    redirect        "..."
```

```
source "unix" {
pass ... !"aggressive" ...
```

### 8.13 Monitoring

Starting with version 1.24, ufdbGuard has two monitoring options: monitoring by email and monitoring by execution of an external command.

ufdbGuard maintains a status of itself and whenever the status changes, it may send an email message to a configurable email address and/or execute a configurable external command. The external command can be any program or script. Usually it is a script that can send an appropriate command for a monitoring tool. By default, ufdbguardd does not send emails and does not execute external commands.

The status values are *started*, *reloading*, *reloaded*, *error* and *terminated*.

#### 8.13.1 Monitoring by Email

The configuration parameters to enable monitoring by email are:

```
mail-server "hostname"
admin-email "email-address"
```

The mail server must accept SMTP connections on port 25. ufdbguardd uses the email address specified with `admin-email` as both the sender and the recipient address.

The subject and content of the email message are:

```
ufdbGuard on hostname has new status: status
database status: dbstat
license status: licinfo
```

The *status* can have one of the following values: *virgin*, *started*, *terminated*, *reloading*, *reloaded* or *error*. The *dbstat* is a text about the URL database and looks like this:

```
up to date
one or more tables are more than 4 days old. Check cron job for ufdbUpdate.
one or more tables are EXPIRED. Check licenses and cron job for ufdbUpdate.
```

The *licinfo* is a self-explanatory text about the license. It may contain a text with the words OK, warning or expired. Warnings are given for licenses that will expire in 2 months or less.

#### 8.13.2 Monitoring by Command Execution

The configuration parameter to enable monitoring by command execution is:

```
external-status-command "path-to-executable"
```

The command must be specified including the full path, e.g. `/usr/local/bin/ufdbmon`. When executed, the program will receive the parameters `-s status -d dbstat -l licinfo`.

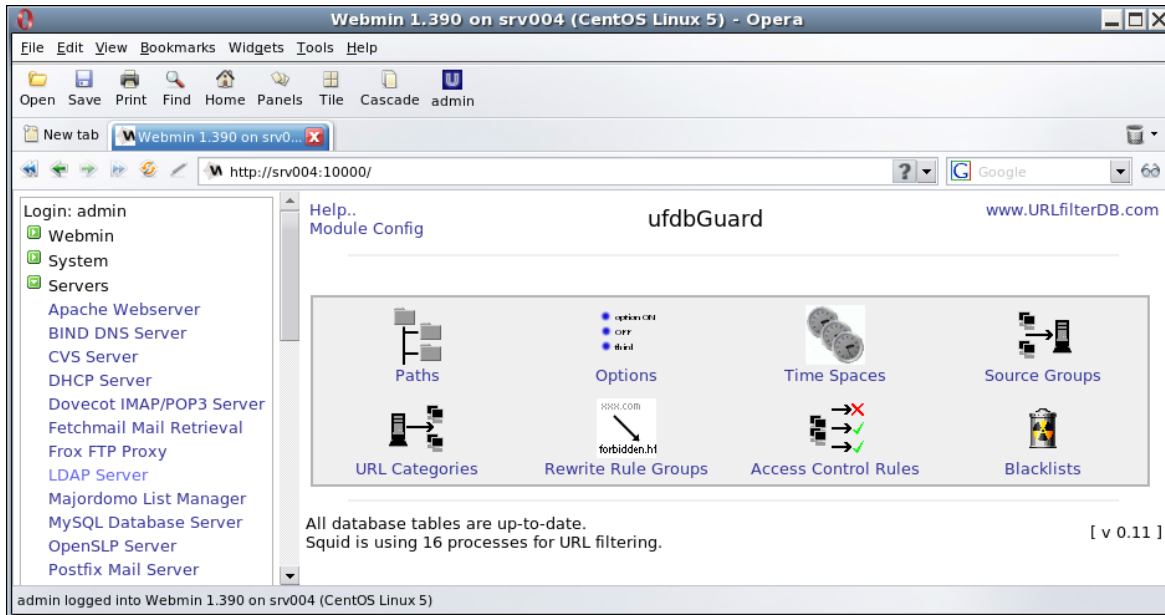

See the previous section for an explanation about *status*, *dbstat* and *licinfo*.

## 9 Web-based configuration

ufdbGuard can be configured easily by editing the configuration file `ufdbGuard.conf`. Alternatively, the web-based configuration can also be used. The web-based configuration is a module for webmin (see [www.webmin.com](http://www.webmin.com)). Expand the *Servers* in the list of webmin modules on the left pane. The ufdbGuard module is at the bottom of the list of the Server modules.

On first usage of the ufdbGuard module for webmin, a check is performed that Squid is using ufdbGuard for URL filtering and offers the option to automatically adjust the configuration of Squid to do so.

After the initial check, the main ufdbGuard configuration window appears (see the next figure). Always configure the main parameters first and Click on *Module Config* in the left upper corner. After the module configuration the other parameters can be defined. The first parameters to define are the paths.

main webmin/ufdbGuard configuration window

The main window offers the configuration of the following items.

**Paths** define directories for the URL database and the log files

**Options** define various options

**Time Spaces** optionally define time slot rules for internet access

**Source Groups** define user groups

**URL Categories** a list of predefined URL categories which can be extended with locally defined URL categories (e.g. alwaysallow)

**Rewrite Rule Groups** optionally define URL rewrite rules

**Access Control Rules** define the ACLs: which user groups are blocked by which URL categories

**Blacklists** Edit user-defined URL blacklists (e.g. alwaysallow)

**View Log** A simple viewer that shows the last 2500 lines of the log files.

## 10 Performance Tuning

### 10.1 Web Proxy Infrastructure

For those organisations that use internal websites, it is recommended to configure and use PAC files that instruct browsers to connect directly to internal servers bypassing Squid and a URL filter. This offloads Squid and usually makes browsing more responsive.

Browsers itself have a cache. The default value for the size of the cache can be very large and it is recommended to set it to a reasonable value, e.g. 100 MB. Note that smaller browser caches usually make the browser faster due to less cache management. A very small cache may make the browser inefficient.

## 10.2 Upgrade C libraries

UNIX distributions that have a glibc 2.3.4<sup>5</sup> or older are recommended to be upgraded. This is due to a bug in the regular expression matching subroutines in the standard C library which is fixed in glibc 2.3.5. On the older systems, ufdbguardd will work flawlessly but at the expense of a performance penalty since only one single thread is allowed to perform lookups based on regular expressions at any point in time. Since ufdGuard cannot distinguish version 2.3.4 from 2.3.5 but can distinguish version 2.3.x from 2.4.x, an upgrade to glibc version 2.4 or higher is recommended.

## 10.3 Squid performance

The following is recommended to improve the performance of Squid:

- use Linux 2.6 instead of earlier versions since the multithreading code in the libraries and kernel is much more efficient.
- use the `noatime` mount option for the file system with the cache. If `reiserfs` is used, also use the `notail` mount option. All options reduce the number of I/Os to the disk.
- use squid 3.1.23 or newer since older versions have too many known issues. Although Squid 3.2.6 has been released, Squid 3.2.x is still considered not stable enough for use in a production environment. In case that you compile Squid, configure it to use `epoll` (`--enable-epoll`) or `kqueue` (`--enable-kqueue`).
- make sure that Squid can use a proper number of open files. You may need to use the `ulimit` command and configure the kernel. There is no official guideline for a proper value for the number of open files, but you may find that  $100+2.5*NUSERS$  with a minimum of 1024, is appropriate. Squid versions 2.7 and 3.1 have a new configuration parameter `max_filedescriptors` which can be added to `squid.conf`.
- use a moderately sized disk cache; a very large cache might have a slightly larger cache hit ratio, but the housekeeping of the cache requires more memory and CPU resources. Note that a larger number of cached objects also requires more physical memory for the index.
- use more than one disk for the disk cache, use only one cache directory per disk and do not stripe unless you are using an advanced disk array with internal striping.
- For optimal I/O performance, use the `aufs` cache directory type, but use `diskd` on FreeBSD.
- Squid does a lot of translations of hostnames to IP addresses and the translations are done by first trying to translate to an IPv6 address and if that does not work to translate to an IPv4 address. If the infrastructure does not have IPv6 routers, disabling IPv6 on the host where Squid runs will give a performance gain because the IPv6 lookups and nameserver delays are prevented.
- Use a moderately sized memory cache. Allow enough memory for the kernel's file system cache and other processes. Remember that the configuration parameter `cache_mem` specifies only the amount of memory to be used for objects and the total process size is usually 3 times the amount of `cache_mem`. So, for a machine with 2 GB memory which only runs Squid, a good starting value for `cache_mem` is 400 MB (Squid will occupy about 1.2 GB).

---

<sup>5</sup> consult your system documentation on how to retrieve version information about the glibc library

- Experiment with a memory-cache only (disable the disk cache) on large memory systems to get rid of the delays of I/O to disk. The benefit of not having disk I/O is usually bigger than the increased bandwidth usage caused by a reduced cache hit ratio. Note that this only works well with a suitable sized internet connection.
- on systems based on Intel CPUs, disable hyperthreading and use only real CPU cores.
- do not forget to run “squid -k rotate” from cron as user squid because it also does important housekeeping of the cache. Perform the housekeeping on a moment when Squid is not used much, preferably in the middle of the night.
- visit <http://wiki.squid-cache.org> for more tips.

## 10.4 Linux 2.6 performance

There are various sources for Linux system tuning and this section is not a replacement. This section contains recommendation for tuning Linux systems that runs Squid and ufdbguardd only.

### 10.4.1 Optimize System Memory Usage

Linux has various settings that control allocation of memory and how the system behaves when real memory gets scarce. Below are given the setting that gave satisfactory system behavior on our test systems.

Add to `/etc/sysctl.conf` the following lines:

```
# swappiness can have a value of between 0 and 100
# swappiness=0 tells the kernel to avoid swapping processes out of physical
# memory for as long as possible
# swappiness=100 tells the kernel to aggressively swap processes out of
# physical memory and move them to swap cache
# default: 60
# For an application server we use a less aggressive setting of 15.
vm.swappiness=15

# VFS cache pressure:
# default: 100
# With values lower than 100, the data cache is reduced more and the
# inode cache preserved
vm.vfs_cache_pressure=50

# Overcommit or not memory allocations:
# 2      Don't overcommit. The total address space commit
#        the system is not permitted to exceed swap + a
#        percentage (default is 50) of physical RAM.
#        on the percentage you use, in most situations
#        means a process will not be killed while accessing
#        but will receive errors on memory allocation as
#        appropriate.
#        Also ensure that the size of swap is at least 75%
#        of physical RAM with a minimum of 2 GB.
vm.overcommit_memory=2
```

Run the following command to make the new configuration active:

```
# sysctl -p /etc/sysctl.conf
```

## 10.4.2 Bind ufdbguardd to a Fixed Set of Processors

For large sites that have both Squid and ufdbGuard running on a system with Linux 2.6 and with 2 or more real CPU cores, additional performance can be gained by optimizing the CPU cache efficiency. By separating the squid and ufdbguardd processes over different CPUs with their own memory caches, the individual CPU caches are used in an optimal way.

Squid is a very CPU intensive application and we reserve CPU 0 for Squid. By configuring ufdbGuard to use the other CPUs, the kernel will move squid automagically to CPU 0. The remaining CPUs can be used by ufdbguardd and the process is bound to these remaining CPUs by including the `cpus` keyword in the ufdbGuard.conf file.

<i>system</i>	<i>for optimal performance, use</i>
2 simple CPUs	<code>cpus 1</code>
2 Xeon CPUs without hyperthreading	<code>cpus 1</code>
2 Xeon CPUs with hyperthreading	<code>cpus 2,3</code>
4 simple CPUs	<code>cpus 2,3</code>
1 dual core	<code>cpus 1</code>
2 dual core	<code>cpus 2,3</code>
1 quad core	<code>cpus 2,3</code>
dual quad core	<code>cpus 4,5,6,7</code>

UfdbGuard and Squid use large amounts of memory and therefore the CPU caches are flushed many times. Always try to separate Squid from ufdbGuard and do not let ufdbGuard use more than 50% of the CPU cores. When in doubt, ask the support desk of URLfilterDB for advice.

## 10.5 Solaris Performance

Use a multi-core system and use a processor set of 2 or more CPUs for Squid and ufdbGuard, and disable interrupts for the CPUs of this processor set. On systems with many cores, use 2 cores for Squid and 2 cores for ufdbGuard.

# 11 Analysis of User Behavior

To learn more about which types of websites are visited by the users and how much bandwidth they use, the tool ufdbAnalyse can assist.

ufdbAnalyse reads one or more Squid log files, strips all non-relevant and personal information, and uploads the URLs to the servers of URLfilterDB for analysis. The stripped result file has no details about persons, passwords, session parameters or times, and the processing is done in compliance with our privacy policy (see section 14).

The support desk will send an email with the outcome of the analysis. The output contains for each URL category the #URLs, percentage of URLs, Kbytes and percentage of Kbytes. An example of the output is below.

The log files contain 51479 lines of which 2250 contain HTTP error codes. 49229 lines were processed for URLfilterDB categories.

Category	#URLs	%	KB	%
Adult	1935	4.0	78204	15.7
Audio & video	128	0.3	58207	11.7
Advertisements	2449	5.0	2296	0.5
Chat	18	0.1	56	0.1
Dating & Personals	190	0.4	4425	0.9
Drugs	0	0.0	0	0.0
Entertainment	6379	13.0	59174	11.9
External Applications	0	0.0	0	0.0
Finance & Investment	1623	3.3	12780	2.6
Forums	152	0.3	817	0.2
Gambling	119	0.3	482	0.1
Games	413	0.9	2565	0.6
Illegal	0	0.0	0	0.0
Jobs	357	0.8	3042	0.6
News	2055	4.2	22224	4.5
Weblogs & private sites	882	1.8	5902	1.2
Peer-to-peer	0	0.0	0	0.0
Web Proxies	148	0.3	812	0.2
Security violations	0	0.0	0	0.0
Shops	3733	7.6	32542	6.5
Social Networks	0	0.0	0	0.0
Sports	813	1.7	6938	1.4
Toolbars	23	0.1	290	0.1
Travel	2586	5.3	21847	4.4
Hacking & warez	9	0.1	89	0.1
Violence & hate	0	0.0	0	0.0
Web-based email	105	0.3	809	0.2
Own domain	1556	3.2	3249	0.7
Allowed sites	23556	47.9	183274	36.7

The `ufdbAnalyse` command uses options to specify the logfile, the own domain, your email address and your full name. The `-l` option may occur up to 64 times to produce a single aggregate report:

```
$ cd /usr/local/ufdbguard/bin
$ ufdbAnalyse -l .../access.log -d example.com -e "me@example.com" -n "John Doe"
```

## 12 Integration with 3rd Party Products

`ufdbGuard` also has an API that allows it to be easily integrated with 3rd party products. With the use of the API, you have access to the core functions of `ufdbGuard` and can perform URL verifications from any program written in C with a very good performance: 90,000 URL verifications per second on an Intel Core 2 Duo CPU (introduced by Intel in 2006). The benchmark was performed with 100,000 URLs using a single 64-bit core on an Intel Core2 E6600 clocked at 2.4 GHz using 9 URL categories: ads, adult, gambling, proxies, p2p, sports, news, webmail, games and warez.

The following diagram gives a simplified overview of how a 3rd party product could operate. In this example, a proxy is linked with the URLfilterDB library for extremely fast URL verifications due to the lack of any inter-process communication overhead.

the URLfilterDB library is part of the web proxy

Alternatively, the next diagram shows any 3rd party can copy the simple code of ufdbgclient and incorporate this in 3rd party software and act as a client to the ufdbguardd daemon.

ufdbGuard daemon processes URL verification requests

You may contact the support desk for additional information and licensing for 3<sup>rd</sup> parties using the URL database.

## 13 Frequently Asked Questions

### **ufdbGuard does not block**

The most common reasons are either a configuration error (check `ufdbguardd.log`) or that the daemon is not active (verify with `ps -ef | grep ufdbguardd`).

Another common reason is that your trial license has expired.

Verify the log file for warning messages. The most serious errors have a 5-star indicator (\*\*\*\*\*).

### **ufdbGuard filters HTTP but not HTTPS**

ufdbGuard filters everything that Squid asks to filter. The most common mistake is to *not use Squid for HTTPS*. Perform a test: browse to <https://www.google.com> and the `access.log` file must have a line with "CONNECT www.google.com:443".

A less common mistake is an error with the Squid configuration parameter `url_rewrite_access`.

### **I want to allow access to site myfavoritesite.com**

See section 7.1. Do not forget to run `ufdbGenTable` after each change.

### **Can I define or add new categories ?**

Yes. The ufdbGuard software suite includes a utility to convert a plain text file into a URLfilterDB database file.

### **Can I use ufdbGuard with a free database?**

The ufdbGuard software is free and can be used with free URL databases if the database is in `.ufdb` format or in an ASCII format. The tools `ufdbGenTable` and `ufdbConvertDB` convert ASCII formatted (flat file) databases to the `.ufdb` format.

### **Which URLs are in the database?**

URLfilterDB does not disclose the content of their database. You are encouraged to test the URL database yourself to find out its effectiveness for your user base. Please refer to section 13.1 for a more detailed description of what you may find in each URL category.

### **What does it cost?**

The URL filter software is free. Prices for a subscription to the URL database are on the website and you can request a quote online. The prices are in EURO and we use a fair exchange rate for countries that prefer to be billed in US dollars. Non-profit and educational institutions receive a 40% discount. Some countries may have lower prices.

### **Any other question**

You may contact the support staff at [support@urlfilterdb.com](mailto:support@urlfilterdb.com) to answer any other question. Always provide as much details as possible and supply a relevant fragment of the log files.

## 13.1 URL Categories

The URL database of URLfilterDB uses the following URL categories.

## **Ads**

Websites with advertisements, traffic trackers and web page counters.

## **P2P**

P2P stands for point-to-point file sharing. The P2P category contains websites that can be used directly or indirectly to upload, download and share files. Most P2P sites have copies of movies, adult content, warez and entertainment, and much content violates copyright.

## **Proxies**

Sites that can be used to download content of other sites, URL rewriting sites and VPNs. Proxies are commonly used in an attempt to circumvent a URL filter and should always be blocked.

## **Adult**

Websites suitable for adults only (not only sexual content).

## **Warez**

Websites with illegal software, illegal software codes, hacker's sites, warez and cracks.

## **Toolbars**

Websites for toolbars of browsers. A toolbar is an extension to a web browser that may violate your privacy or make private files public.

## **Illegal**

Websites explaining how to perform Illegal activities.

## **Violence**

Websites about violent behavior and aggressive sales of arms.

## **Gambling**

Websites offering gambling opportunities.

## **Drugs**

Websites about hard drugs and soft drugs.

## **Webmail**

Email accessible with a web browser. Webmail of business sites is not included. Webmail of ISPs is included in this category.

## **Dating**

Websites about love, dating, romantic poetry, and friendship.

## **Chat**

Websites to use IRC and chat. Subcategories exist for AIM, Ebuddy, Facebook Chat, Google Talk, MSN Messenger, Oovoo, Skype and Yahoo Chat.

## **Forum**

Websites where people exchange non-business information in a forum.

## **Private**

Blogs and sites of private persons.

## **Audio-Video**

Audio and video streams. Many entertainment sites are both in the category entertainment and in audio-video (e.g. [www.youtube.com](http://www.youtube.com)).

## **Sports**

Websites related to sports including sports sections of news sites, fans of sports, sites about actively doing a sport.

## **Finance**

Websites of banks, insurance companies, stock markets and stock brokers.

## **Jobs**

Websites about and for job applications.

## **Games**

Websites to play games and information about gaming.

## **Entertainment**

Entertainment, lifestyle, hobby, arts, museums, food, fashion, electronic cards, magazines, horoscopes, desktop wallpapers, clip art, photos, portals, events, fan sites, baby-related, child sites, file sharing, religion and other sites for interest of private persons that are not related to business.

## **Shops**

Websites with shops, price comparisons, and auctions aimed at consumers (b2b is excluded).

## **Travel**

Websites about travel agencies, airlines, tourism sites, hotels, holiday resorts.

## **News**

Websites providing news and opinions.

## **External Applications**

Free web-based document editors, spreadsheet applications, desktops, groupware, etc. where “internal” documents can be stored on external servers.

## **Security**

This is an administrative category to be able to enforce strict HTTPS usage options (see section 5.4).

## **Social Networks**

Sites that focus on building and reflecting of social networks or social relations among people. Subcategories exist for Badoo, Facebook and Twitter.

## **Checked**

URLs that are verified by URLfilterDB not to be part of any category and hence always are allowed by the URL filter. This category contains business sites, governmental sites and useful sites for the general

public. This administrative category is used by the URL filter to track uncategorized URLs and users should not configure this category.

The URL database is used to block web content and not to classify web content. So, a website that has a business use, is always part of the category “checked” and will never be blocked. For example, access to a website to sell medical equipment for hospitals is always allowed because it is not part of the category “shops”. Also governmental sites, and all sites for basic human needs like electricity, water and housing are never blocked.

The nature of the content is more important than the strict definition, so an advertisement with a nude person is classified as adult rather than advertisement, and a forum about games is classified as games rather than a forum.

The general impression is also taken into account when a site is categorized. For example, most buyers at `ebay.com` are consumers rather than business users and therefore `ebay.com` is considered a shop for consumers and part of the shops category.

URLs may be part of two or more categories, e.g. `www.usatoday.com` is news while `www.usatoday.com/sport` is both news and sports. If a configuration blocks sports and allows news, it may occur that parts of websites are accessible while other parts are not.

## 14 Privacy Policy

The privacy policy of URLfilterDB is stated on the website: [www.urlfilterdb.com/privacystatement.html](http://www.urlfilterdb.com/privacystatement.html).
